# I.1. Three Key Ideas

- *Geometric modeling*

- *Formal approach.*
- *Description first!*

*The model should follow the data, not the reverse!"*

## I.2. Three Paradigms

- *Correspondence Analysis* (CA)  
→ Contingency table
- *Principal Component Analysis* (PCA)  
→ Individuals  $\times$  Numerical Variables table
- *Multiple Correspondence Analysis* (MCA)  
→ Individuals  $\times$  Categorical Variables table

## I.3. Historical Sketch

J.-P. Benzécri (1982)

# Precursors

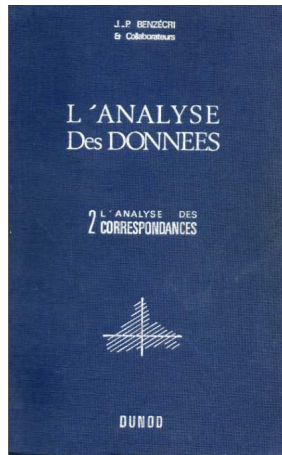

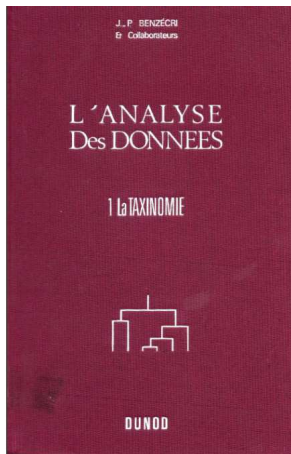

Karl Pearson (1901), Hirschfeld (1935).

*Should we need an Anglo–Saxon patronage for “Analyse des Données”, we would be pleased to turn to the great Karl Pearson.*

Benzécri (1982), p. 116

- Optimal scaling: Fisher (1940), Guttman (1942)
- Factor analysis: Burt (1950)
- Quantification method: Hayashi (1952)
- MDS: Shepard (1962).

# Emergence (1963-73)

Benzécri et al. (1973): L'ANALYSE Des DONNÉES  
1 la TAXINOMIE    2 L'ANALYSE DES CORRESPONDANCES.

# Recognition and splendid isolation (1973-1980)

1977–1997

Gower (1966), Good (1969), Gabriel (1971)  
Ignored in Shepard, Romney, Nerlove (1972), Kruskal & Wish  
(1978), Shepard (1980) and in Kendall & Stuart (1976)

## International recognition (since 1981)

Greenacre (1984), Lebart & al (1984), Jambu (1991),  
Benzécri (1992) (translation of the introductory book  
published by Dunod in 1984);

Malinvaud (1980), Deville & Malinvaud (1983):

*“Econometrics without stochastic models”*

Tenenhaus & Young (1985) : Psychometry;

Nishisato (1980): Dual Scaling;

Gifi (1981/1990): Homogeneity Analysis;

Carroll & Green (1988), Weller & Romney (1990): MDS group;

Gower & Hand (1996): biplot.

# Where do we stand now?

Goodman (1986, 1991), Weller & Romney (1990), Rao (1995).

*CARME network*: international conferences in Cologne (1991, 1995, 1999), Barcelona (2003), Rotterdam (2007), Rennes (2011), Naples (2015) ...

*Workshops* organized in Paris, Uppsala, Copenhagen, Montreux, London, Kaliningrad, Mendoza, Berkeley ...

## Recent Books:

Le Roux & Rouanet  
2004

Murtagh  
2005

CARME  
2003 (2006)

Le Roux & Rouanet  
2010

## Le Roux 2014

## CARME 2011 (2015)

## Lebaron & Le Roux (eds) 2015

CA is now recognized and used, but GDA as a whole methodology, is waiting to be discovered by a large audience.

# II — Principal Axes of a Euclidean Cloud

This text is adapted from Chapter 2 of the monograph  
*Multiple Correspondence Analysis*  
(QASS series n°163, SAGE, 2010)

## II.1. Basic Geometric Notions

Elements of a geometric space: *points, line, plane*.

— *Affine notions*: alignment, direction and barycenter.

Couple of points (P, M), or *dipole*  $\longrightarrow$  *vector*  $\overrightarrow{PM}$

The *deviation* from point P to point M is  $M - P$  (“terminal minus initial”), that is,  $\overrightarrow{PM}$ .

Deviations add up vectorially: sum of vectors by *parallelogram law*

## *Barycenter* of a dipole

$$G = \frac{3A+2B}{5}$$

$$\vec{PG} = \frac{3}{5}\vec{PA} + \frac{2}{5}\vec{PB}$$

Barycenter = *weighted average of points*:  $G = \frac{aA+bB}{a+b}$

— *Metric notions*: distances and angles.

*Triangle inequality*:

$$PQ \leq PM + MQ$$

*Pythagorean theorem*:

If PM and MQ are perpendicular then:

$$(PM)^2 + (MQ)^2 = (PQ)^2$$

(triangle MPQ with right angle at M),

## II.2. Cloud of Points

Figure 1. Target example (10 points)

Figure 1b. Cloud of 10 points with origine-point O and initial axes

Initial coordinates

	$x_1$	$x_2$	weights
$i_1$	0	-12	1
$i_2$	6	-10	1
$i_3$	14	-6	1
$i_4$	6	-2	1
$i_5$	12	0	1
$i_6$	-8	2	1
$i_7$	2	4	1
$i_8$	6	4	1
$i_9$	10	10	1
$i_{10}$	12	10	1
Means	6	0	[10]
Variances	40	52	
Covariance		+ 8	

**Mean point:** point G

$$\overrightarrow{OG} = \sum p_i \overrightarrow{OM}^i \quad \sum p_i \overrightarrow{GM}^i = \vec{0} \text{ (barycentric property)}$$

**Target Example:**  $p_i = \frac{1}{n}$  ( $p_i = \frac{1}{10}$ )

*Variance of a cloud :*

$$V_{\text{cloud}} = \sum p_i (\text{GM}^i)^2$$

(see Benzécri 1992, p.93)

## Property

In rectangular axes, the variance of the cloud is the sum of the variances of the coordinate variables.

*Contribution of point  $M^i$ :*

$$\text{Ctr}_i = \frac{p_i (\text{GM}^i)^2}{V_{\text{cloud}}}$$

## II.3. Principal Axes of a Cloud

### *Projection of a cloud*

$P'$  = projection of point  $P$  onto  $\mathcal{L}$  along  $\mathcal{L}'$

$\vec{P'P}$  = residual deviation

If point  $M$  is the midpoint of  $P$  and  $Q$ , the point  $M'$ , projection of  $M$  on  $\mathcal{L}$ , is the midpoint of  $P'$  and  $Q'$ .

## Mean point property

The mean point is preserved by projection.

*Orthogonal projection*:  $PP'$  is perpendicular to  $\mathcal{L}$ .

The orthogonal projection contracts distances:  $P'Q' \leq PQ$ , therefore one has the

## Property

variance of projected cloud  $\leq$  variance of initial cloud.

## Projected clouds on several lines

variance=40

variance = 52

## Orthogonal additive decomposition

The variance of the initial cloud is the sum of the variances of projected clouds onto perpendicular lines:  $V_{\text{cloud}} = 40 + 52 = 92$ .

Projection onto an oblique line (60 degrees) : variance = 55.9

Variance

$D_1$	$D_2$	$D_3$	$D_4$	$D_5$	$D_6$	$D_1$
52	42.1	36.1	40.0	49.9	55.9	52

The line whose the variance of the projected cloud is maximum is called *first principal line*.

directed line  $\rightarrow$  *1st principal axis*

Projected cloud = *1st principal cloud*

its variance ( $\lambda_1$ ) = *variance of axis 1*

The first principal cloud is *the best fitting* of the initial cloud by an uni-dimensional cloud in the sense of *orthogonal least squares*

Here,  $\alpha = 63^\circ$ ,  $\lambda_1 = 56$ .

One constructs the residual cloud.

The first principal line of the residual cloud defines the *second principal line* of the initial cloud.

Here, the cloud is a plane cloud (two dimensions), hence the *second axis* is simply the perpendicular to the first axis.

Principal representation of the cloud.

## II.4. From a Plane Cloud to a Higher Dimensional Cloud

### Heredity property

The plane that best fits the cloud is the one determined by the first two axes.

High dimensional cloud.

Low dimensional projection.

## II.5. Properties

- **Variance of cloud** = sum of variances of axes:  $V_{\text{cloud}} = \sum \lambda_\ell$ .
- The **principal axes** are *pairwise orthogonal*.  
Each axis can be directed arbitrarily.
- The *principal coordinates* of points define **principal variables**.  
mean = 0 and variance =  $\lambda$  (eigenvalue)  
Principal variables are *uncorrelated* (for distinct eigenvalues).
- **Reconstitution of distances** between points:  
$$d^2(i1, i2) = (-13.4 + 8.9)^2 + (0 - 4.47)^2 = 4.23 = (6.3)^2$$

# Aids to Interpretation

- Quality of fit of an axis or *variance rate*:

$$\frac{\lambda}{V_{\text{cloud}}}$$

- Contribution of point to axis*:

$$\text{Ctr} = \frac{p(y)^2}{\lambda} \quad (p = \text{relative weight, } y = \text{coordinate on axis})$$

- Quality of representation of point onto axis*:

$$\cos^2 \theta = \frac{GP^2}{GM^2}$$

*Example:* for  $i_2$ ,  $\cos^2 \theta = \frac{(-8.94)^2}{100} = 0.80$

# Results of the analysis

$\lambda_1 = 56$  (variance of axis 1, eigenvalue).

$$\text{Variance rate} : \frac{\lambda_1}{V_{\text{cloud}}} = \frac{56}{92} = 61\%$$

## Results for axis 1

## Results for axis 2

		$\lambda_1 = 56$			$\lambda_1 = 36$

# III — Multiple Correspondence Analysis (MCA)

This text is adapted from Chapter 3 of the monograph  
*Multiple Correspondence Analysis*  
(QASS series n°163, SAGE, 2010)

## III.1. Introduction

Language of questionnaire

Basic data set: **Individuals** × **Questions** table

- **Questions** = categorical variables, i.e. variables with a finite number of *response categories*, or *modalities*.
- **Individuals** or “statistical individuals”: (people, firms, items, etc.).

### “*Standard format*”

for each question, each individual chooses *one and only one* response category.

→ otherwise: preliminary phase of *coding*

## III.2. Principles of MCA

### Notations:

$I$ : set of  $n$  individuals;

$Q$ : set of questions

$K_q$ : set of categories of question  $q$  ( $K_q \geq 2$ )

$K$ : overall set of categories

$n_k$ : number of individuals who have chosen category  $k$   
(absolute frequency)

$f_k = \frac{n_k}{n}$  (relative frequency)

Table analyzed by MCA:  $I \times Q$  table

MCA produces two clouds of points:

the *cloud of individuals* and the *cloud of categories*.

## III.3. Taste example

A row corresponds to the *response pattern* of an individual

## III.4. Cloud of Individuals

Distance between 2 individuals due to question  $q$ :

— if  $q$  is an **agreement question**:  $i$  and  $i'$  choose the same category

$$d_q(i, i') = 0$$

— if  $q$  is a **disagreement question**:  $i$  chooses category  $k$  and  $i'$  chooses category  $k'$ :

$$d_q^2(i, i') = \frac{1}{f_k} + \frac{1}{f_{k'}}$$

**Overall distance:**  $d^2(i, i') = \frac{1}{Q} \sum_{q \in Q} d_q^2(i, i')$

individual  $i \longrightarrow$  point  $M^i$  with relative weight  $p_i = \frac{1}{n}$

G: mean point (center) of the cloud

$$(GM^i)^2 = \left( \frac{1}{Q} \sum_{k \in K_i} \frac{1}{f_k} \right) - 1 \quad (K_i: \text{response pattern of individual } i).$$

## Variance of the cloud of individuals

$$V_{\text{cloud}} = \frac{K}{Q} - 1$$

(average number of categories per question minus 1).

## III.5. Cloud of Categories

**Distance** between categories  $k$  and  $k'$ :  $d^2(k, k') = \frac{n_k + n_{k'} - 2n_{kk'}}{n_k n_{k'}/n}$

$n_k$  = number of individuals who have chosen  $k$  (resp.  $n_{k'}$ );

$n_{kk'}$  = number of individuals who have chosen both categories  $k$  et  $k'$ .

category  $k \rightarrow$  category–point  $M^k$  with relative weight  $p_k = f_k/Q$

### Property

$G$  is the mean point of the category–points of any question.

$$(GM^k)^2 = \frac{1}{f_k} - 1.$$

- **Variance of the cloud of categories:**  $= \frac{K}{Q} - 1.$

- **Contributions**

Contribution of category  $k$

$$\text{Ctr}_k = \frac{1-f_k}{K-Q}$$

Contribution of question  $q$

$$\text{Ctr}_q = \frac{K_q-1}{K-Q}$$

## III.6. Principal Clouds

### — *Principal axes*

#### Fundamental properties

- The two clouds have the same variances (eigenvalues).

- $\sum_{\ell=1}^L \lambda_{\ell} = V_{\text{cloud}}$ , with  $\bar{\lambda} = \frac{V_{\text{cloud}}}{L} = \frac{1}{Q}$ .

### — *Variance rates and modified rates*

Variance rate:

$$\tau_{\ell} = \frac{\lambda_{\ell}}{V_{\text{cloud}}}$$

Modified rate:

$$\tau'_{\ell} = \frac{\lambda'_{\ell}}{S}, \text{ with } \lambda'_{\ell} = \left(\frac{Q}{Q-1}\right)^2 (\lambda_{\ell} - \bar{\lambda})^2 \text{ and } S = \sum_{\ell=1}^{\ell_{\max}} \lambda'_{\ell}$$

## — *Principal coordinates and principal variables*

$y_\ell^i$ : coordinate of individual  $i$  on axis  $\ell$

$y_\ell^I = (y_\ell^i)_{i \in I}$ :  $\ell$ -th principal variable over  $I$

$y_\ell^k$ : coordinate of category  $k$  on axis  $\ell$

$y_\ell^K = (y_\ell^k)_{k \in K}$ :  $\ell$ -th principal variable over  $K$

## Properties

Mean of principal variable is null:

$$\sum \frac{1}{n} y_\ell^i = 0 \text{ and } \sum p_k y_\ell^k = 0$$

Variance of principal variable  $\ell$  is equal to  $\lambda_\ell$ :

$$\sum \frac{1}{n} (y_\ell^i)^2 = \lambda_\ell \text{ and } \sum p_k (y_\ell^k)^2 = \lambda_\ell$$

Principal variables are pairwise uncorrelated:

$$\ell \neq \ell' \quad \sum y_\ell^i y_{\ell'}^i = 0 \quad \sum y_\ell^k y_{\ell'}^k = 0$$

## III.7. Aids to Interpretation: Contributions

Contribution of category–point  $k$  to axis  $l$ :  $\frac{p_k (y_l^k)^2}{\lambda l}$

( $y$ : coordinate of point on axis;  $p$ : relative weight;  $\lambda$ : variance of axis)

By grouping, contributions add up  $\rightarrow$  contribution of question...

The quality of representation of point  $M^k$  on Axis  $\ell$  is

$$\cos^2 \theta_{k\ell} = \frac{(GM_\ell^k)^2}{(GM^k)^2} = \frac{(y_\ell^k)^2}{(GM^k)^2}$$

## — Category mean points

$\bar{M}^k$ : category mean point for  $k$  with coordinate on axis  $\ell$

$$\bar{y}_\ell^k = \sqrt{\lambda_\ell} y_\ell^k \quad (\text{second transition formula})$$

The  $K$  category mean points of question  $q$  define the  
**between- $q$  cloud**

.

## — Supplementary elements:

individuals and/or questions

## III.8. MCA of the Taste Example

### Data set

The data involve:

- $Q = 4$  active variables
- $K = 8 + 8 + 7 + 6 = 29$  categories
- $n = 1215$  individuals

Overall variance of the cloud :  $V_{\text{cloud}} = \frac{29}{4} - 1 = 6.25$

Contributions of questions to the overall variance:

$$\frac{8-1}{29-4} = 28\% \quad 28\% \quad 24\% \quad 20\%$$

# Elementary statistical results

$8 \times 8 \times 7 \times 6 = 2688$  possible response patterns; 658 are observed.

# Cloud of categories in plane 1-2

## Cloud of individuals in plane 1-2.

## III.9. Transition Formulas

Transition formulas express the *relation* between  
the *cloud of individuals*  
and  
the *cloud of categories*.

## • First transition formula

cloud of categories  $\longrightarrow$  cloud of individuals:  $y^i = \frac{1}{\sqrt{\lambda}} \sum_{k \in K_i} y^k / Q$

*Category–point  $k$  is located at the equibarycenter of the  $n_k$  individuals who have chosen category  $k$ , up to a stretching along principal axes.*

In terms of coordinates:

- 1 mean of the 4 coordinates on axis 1:

$$\frac{-0.881 - 1.328 - 1.038 - 1.270}{4} = -1.12925$$

mean of the 4 coordinates on axis 2:

$$\frac{-0.003 - 0.037 - 0.747 - 0.488}{4} = -0.31875$$

- 2 dividing the coordinate on axis 1 by  $\sqrt{\lambda_1}$ :

$$y_1^i = \frac{-1.12925}{\sqrt{0.4004}} = -1.785$$

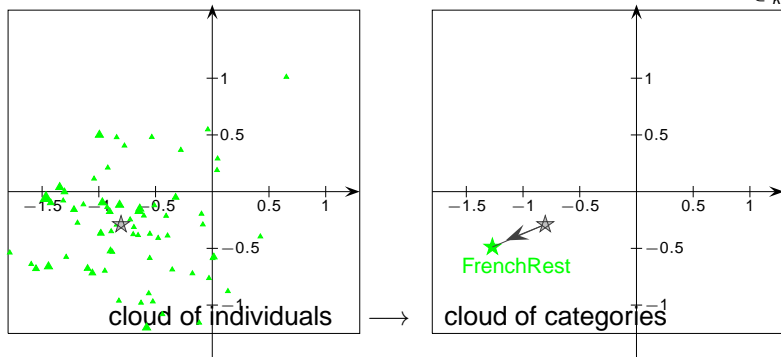

dividing the coordinate on axis 2 by  $\sqrt{\lambda_2}$

$$y_2^i = \frac{-0.31875}{\sqrt{0.3512}} = -0.538$$

which are the coordinates of the *individual-point* #235 .

## • Second transition formula

cloud of individuals  $\longrightarrow$  cloud of categories:  $y^k = \frac{1}{\sqrt{\lambda}} \sum_{i \in I_k} y^i / n_k$

Individual–point is located at the equibarycenter of the  $Q$  category–points of his response pattern, up to a stretching along principal axes.

## III.10. Interpretation of the Analysis of the Taste Example

*How many axes need to be interpreted?*

Axis 1:  $(\frac{\lambda_1 - \lambda_2}{\lambda_1} = .12)$ ; modified rate = 0.48

Axis 2:  $(\frac{\lambda_2 - \lambda_3}{\lambda_2} = .07)$ ; modified rate = 0.22.

Cumulated modified rate for axes 1 and 2 = 0.70.

After axis 4, variances decrease regularly and the differences are small.

1	0.4004	6.41	0.48
2	0.3512	5.62	0.22
3	0.3250	5.20	0.12
4	0.3081	4.93	0.07
5	0.2989	4.78	0.05
6	0.2876	4.60	0.03

Cumulated modified rate for for axes 1, 2 and 3 = 82%

## Guide for interpreting an axis

*Interpreting an axis amounts to finding out what is similar, on the one hand, between all the elements figuring on the right of the origin and, on the other hand between all that is written on the left; and expressing with conciseness and precision, the contrast (or opposition) between the two extremes.*

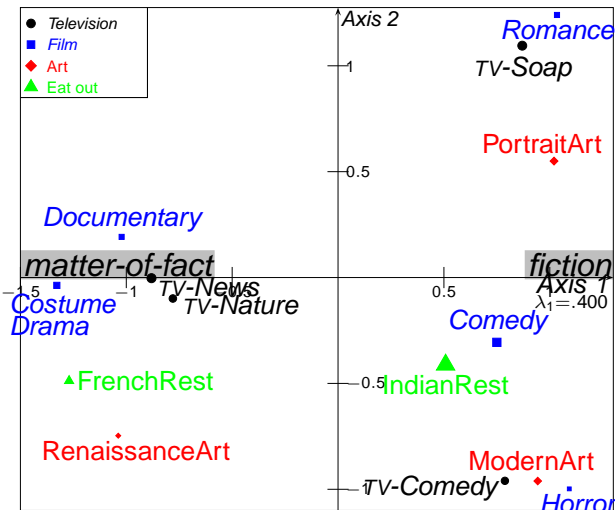

Benzécri (1992, p. 405)

For interpreting an axis, we use the method of contributions of points and deviations.

Baseline criterion = average contribution =  $100/29 \rightarrow 3.4\%$

The interpretation of an axis is based on the categories whose contributions to axis exceed the average contribution.

## Interpretation of axis 1

● TV (31%) *left* *right*

TV-News	8.8	
TV-Soap		8.4
TV-Nature	4.9	
TV-Comedy		4.9

■ Film (35%)

Cost. Drama	12.7	
Comedy		6.8
Romance		5.5
Documentary	5.4	
Horror		3.8

◆ Art (19%)

Portrait	6.3	
Modern		5.0
Renaissance	3.0	

▲ Eat out (15%)

French Rest.	8.2	
Indian Rest.		5.3

Total: 43.0 + 46.0 = 89.0

14 categories selected for the interpretation of axis 1: sum of contributions = 89% → *good summary*

- Axis 1 opposes *matter-of-fact* (and traditional) tastes to *fiction world* (and modern) tastes.
- Axis 2 opposes *popular* to *sophisticated* tastes.
- Axis 3 opposes *outward dispositions* to *inward ones*.

# Supplementary individuals

Plane 1-2. Cloud of 38 Indian immigrants with its mean point (★).

# LOCATE YOURSELF

## Supplementary variables

	weight	Axis 1	Axis 2	Axis 3
Men	513	-0.178	-0.266	+0.526
Women	702	+0.130	+0.195	-0.384
18-24	93	+0.931	-0.561	+0.025
25-34	248	+0.430	-0.322	-0.025
35-44	258	+0.141	-0.090	+0.092
45-54	191	-0.085	-0.118	-0.082
55-64	183	-0.580	+0.171	-0.023
≥ 65	242	-0.443	+0.605	+0.000

		Income		
	weight	Axis 1	Axis 2	Axis 3
< \$9 000	231	+0.190	+0.272	+0.075
\$10-19 000	251	-0.020	+0.157	-0.004
\$20-29 000	200	-0.038	-0.076	+0.003
\$30-39 000	122	-0.007	-0.071	-0.128
\$40-59 000	127	+0.017	-0.363	+0.070
> \$60 000	122	-0.142	-0.395	-0.018
"unknown"	162	-0.092	+0.097	-0.050

*As a rule of thumb:*

- a deviation greater than 0.5 will be deemed to be “**notable**”;
- a deviation greater than 1, definitely “**large**”.

Supplementary questions in plane 1-2 (top), and in plane 2-3 (bottom) (cloud of categories).

# IV — What is Cluster Analysis?

*Reference:*

B. Le Roux, *L'analyse géométrique des données multidimensionnelles*, Dunod 2014, Chapters 10 & 11.

## IV.1. The Aim of Cluster Analysis

Construct homogeneous clusters of objects (in GDA subclouds of points) so that:

- objects within a same cluster are as much similar as possible: *compactness* criterion;
- objects belonging to different clusters are as little similar as possible: *separability* criterion;

The greater the similarity (or homogeneity) within a cluster and the greater the difference between clusters the better the clustering.

heterogeneity between clusters — homogeneity within clusters

# Types of Clustering

- 1 algorithms leading to **partitions**.  
Partitional clustering decomposes a data set into a set of disjoint clusters.  
two following requirements:
  - 1) each group contains at least one point,
  - 2) each point belongs to exactly one group.**clustering around moving centers** or **K-means cluster analysis**.
- 2 algorithms leading to **hierarchical hierarchy** (the paradigm of natural sciences): system of nested clusters represented by a hierarchical tree or *dendrogram*.
  - ▶ **ascending** algorithms (AHC)
  - ▶ **descending** algorithms (segmentation methods):  
problems of discrimination and regression by gradual segmentation of the set of objects → binary decision tree

The methods of type 1 are *geometric* methods.

The method of type AHC is *geometric* if the distance is Euclidean and the aggregation index is the variance index.

The methods of type "segmentation" are not geometric.

The number of partitions into  $k$  clusters of  $n$  objects

$n$		$k$		
5 objects	into	2 clusters	=	15
10 objects	into	2 clusters	=	511
10 objects	into	5 clusters	=	42 525

etc.

it is impossible to enumerate all the partitions of a set of  $n$  individuals into  $k$  clusters

## IV.2. Partition of a Cloud: Between– and Within–variance

- Subclouds

*A*: subcloud of 2 points (dipole)  
 $\{i1, i2\}$

*B*: subcloud of 1 point  
 $\{i6\}$

*C*: subcloud of 7 points  
 $\{i3, i4, i5, i7, i8, i9, i10\}$

Partition of a cloud into 3 subclouds:  $A$ ,  $B$  and  $C$ .

3 mean points  $A$ ,  $B$ ,  $C$  with weights  $2$ ,  $1$ ,  $7$ .

By grouping:

- points “average up”
- weights add up

	weights	Coordinates		variances
		$x_1$	$x_2$	
$A$	$n_A = 2$	3	-11	10
$B$	$n_B = 1$	-8	2	0
$C$	$n_C = 7$	8.857	2.857	46.57
	$n = 10$	$\bar{x}_1 = 6$	$\bar{x}_2 = 0$	34.6

The mean of the variances of subclouds is the *within-variance*

# Between-cloud

The 3 mean points (A,2), (B,1) et (C,7) define the *between-cloud*.

The between-cloud is a weighted cloud;

- its total weight is  $n = 10$ ;
- its mean point is G;
- its variance is  $\frac{2}{10}(GA)^2 + \frac{1}{10}(GB)^2 + \frac{7}{10}(GC)^2 = 57.4$   
and called *between-variance*

## Contributions of a subcloud

The *contribution of a subcloud* is the sum of the contributions of its points.

The *within-contribution* of a subcloud is the product of its weight by its variance and divided by  $V_{\text{cloud}}$ .

— *Example*: subcloud  $\mathcal{A}$

$$\text{Ctr}_{i1} = \frac{\frac{1}{10}(\text{GM}^{i1})^2}{92} = \frac{\frac{1}{10} \times 180}{92} = \frac{18}{92}; \quad \text{Ctr}_{i2} = \frac{\frac{1}{10}(\text{GM}^{i2})^2}{92} = \frac{\frac{1}{10} \times 100}{92} = \frac{10}{92}$$

- contribution of the *subcloud*:  $\text{Ctr}_{\mathcal{A}} = \frac{18}{92} + \frac{10}{92} = \frac{28}{92}$
- contribution of the *mean point*:  $\text{Ctr}_{\mathcal{A}} = \frac{\frac{2}{10} \times 130}{92} = \frac{26}{92}$
- *within-contribution*:  $\frac{\frac{2}{10} \times 10}{92} = \frac{2}{92}$

## Huyghens theorem

The contribution of a subcloud is the sum of the contribution of its mean point and of its within-contribution.

*Example:* Subcloud  $A$

$$\text{Ctr}_A = \text{Ctr}_A + \text{within-contribution}$$

$$\frac{28}{92} = \frac{26}{92} + \frac{2}{92}$$

# Between–within decomposition of variance

	Ctr $\times$ $V_{\text{cloud}}$		subclouds
	mean points	within	
<i>A</i>	26.0	2.0	28
<i>B</i>	20.0	0	20
<i>C</i>	11.4	32.6	44
Total	57.4	34.6	92
Variance	between	within	total

## Within-variance

= sum of within–contributions  $\times V_{\text{cloud}}$

= weighted mean of variances of subclouds ( $\frac{2}{10} \times 10 + 0 + \frac{7}{10} \times 46.6$ )

= 34.6

Total variance = between-variance + within-variance

$$\eta^2 = \frac{\text{between-variance}}{\text{total variance}} \text{ (eta-square)}$$

## Subcloud of 2 points (dipole)

A and B weighted by  $n_A = 2$  and  $n_B = 1$  with mean point  $G'$ .

Weight of dipole :  $\widetilde{n}_{AB} = 1 / \left( \frac{1}{n_A} + \frac{1}{n_B} \right)$

Absolute contribution:  $p \times d^2$  with  
 $p = \frac{\widetilde{n}_{AB}}{n}$  (relative weight) and  $d^2 = AB^2$  (square of the deviation).

*Example:* dipole {A, B}.

$$AB^2 = 290$$

$$\widetilde{n}_{AB} = \frac{1}{\frac{1}{1} + \frac{1}{2}} = 2/3, \quad p = \frac{2/3}{10} = 0.06667$$

Absolute contribution:

$$0.06667 \times 290 = 19.33$$

### Property

The absolute contribution of a dipole is the absolute contribution of the subcloud of its two points.

## IV.3. $K$ -means Clustering

or aggregation around *moving centers*

- 1 Fix the number of clusters, say  $C$ ;
- 2 Choose (randomly or not)  $C$  initial class centers;
- 3 Assign each object to the closest center  $\rightarrow$  new clusters;
- 4 Determine the centers of the new clusters;
- 5 Repeat the assignment;
- 6 Stop the algorithm when 2 successive iterations provide the same clusters.

Choose 2 initial centers:  $M^{c_0}$  and  $M^{c'_0}$

## IV.4. Ascending Hierarchical Clustering (AHC)

Clusters =

either the objects to be clustered (one–element class),  
or the clusters of objects generated by the algorithm.

At each step, one groups the two elements which are the closest, hence the representation by a *hierarchical tree* or dendrogram.

We have to define the notion of “close”, that is, the *aggregation index*.

## Ascending/agglomerative Hierarchical Clustering:

starting with the basic objects (one–element clusters) proceed to successive aggregations until all objects are grouped in a single class.

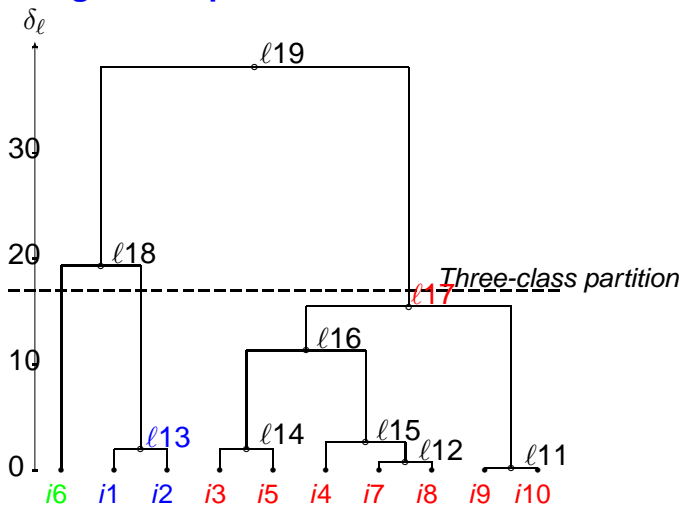

Once an aggregation index has been chosen, the *basic algorithm* of AHC is as follows:

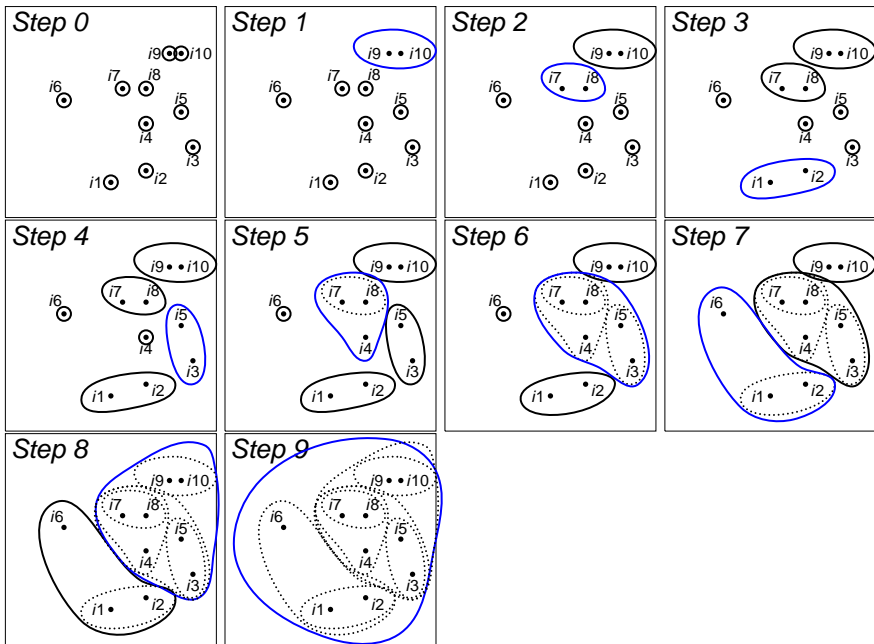

**Step 1.** From the table of distances between the  $n$  objects, calculate the aggregation index for the  $n(n - 1)/2$  pairs of one–element clusters, then aggregate a pair of clusters for which the index is minimum: hence a partition into  $J - 1$  clusters.

**Step 2.** Calculate the aggregation indices between the new class and the  $n - 2$  others, and aggregate a pair of clusters for which the index is minimum  $\rightarrow$  second partition into  $n - 2$  clusters in which the first partition is nested.

**Step 3.** Iterate the procedure until a single class is reached.

## Target example: hierarchical tree

## IV.5. Euclidean Clustering

- 1 Objects = *points of Euclidean cloud*.
- 2 *Aggregation index* = variance index, that is, the contribution of the dipole of the class centers (Ward index).

### Grouping property

If 2 clusters are *grouped*, the between–variance *decreases* from an amount equal to the contribution of the dipole constituted of the centers of the 2 grouped clusters.

# Basic Algorithm

- **Step 1.** Calculate the contributions of the  $9 \times 10/2 = 45$  dipoles

*Example:* For dipole  $\{i1, i2\}$ :

$$\tilde{n}_{12} = 1 / \left( \frac{1}{7} + \frac{1}{7} \right) = 0.5;$$

$$\text{squared distance} = (0 - 6)^2 + (-12 + 10)^2 = 40;$$

$$\rightarrow \text{absolute contribution of dipole} = \frac{0.5}{10} \times 40 = 2.$$

$\delta$	<i>i1</i>	<i>i2</i>	<i>i3</i>	<i>i4</i>	<i>i5</i>	<i>i6</i>	<i>i7</i>	<i>i8</i>	<i>i9</i>
<i>i2</i>	2								
<i>i3</i>	11.6	4							
<i>i4</i>	6.8	3.2	4						
<i>i5</i>	14.4	6.8	2	2					
<i>i6</i>	13	17	27.4	10.6	20.2				
<i>i7</i>	13	10.6	12.2	2.6	5.8	5.2			
<i>i8</i>	14.6	9.8	8.2	1.8	2.6	10	0.8		
<i>i9</i>	29.2	20.8	13.6	8	5.2	19.4	5	2.6	
<i>i10</i>	31.4	21.8	13	9	5	23.2	6.8	3.6	0.2

Minimum index **0.2** for the pair of points  $\{i_9, i_{10}\}$  which are aggregated (fig. 1), hence the mean point  $\ell_{11}$  and a derived *cloud of 9 points* (fig. 2).

Figure 1

- **Step 2.** Calculate the aggregation index between the new point  $l_{11}$  and the 8 other points.

New minimum 0.8 for  $\{i7, i8\}$  which aggregated (fig. 2), hence the new point  $l_{12}$  and a derived *cloud of 8 points* (fig. 3).

	$i1$	$i2$	$i3$	$i4$	$i5$	$i6$	$i7$	$i8$
$l_{11}$	40.33	28.33	17.67	11.27	6.73	28.33	7.8	4.07

Figure 2

• **Step 3.** Iterate the procedure

Aggregation index between  $l_{12}$  and the 7 other points

	$i_1$	$i_2$	$i_3$	$i_4$	$i_5$	$i_6$	$l_{11}$
$l_{12}$	18.13	13.33	13.33	2.67	5.33	9.87	8.2

Minimum = 2 for  $\{i_1, i_2\}$ ,  $\{i_3, i_5\}$  and  $\{i_4, i_5\}$ , aggregation of  $i_1$  and  $i_2$  (fig. 3), hence the point  $l_{13}$  and a *cloud of 7 points* (fig. 4).

Figure 3

• **Step 4.** Iterate the procedure

Aggregation index between  $l_{13}$  and the 6 other points

	$i_3$	$i_4$	$i_5$	$i_6$	$l_{11}$	$l_{12}$
$l_{13}$	9.73	6.00	13.47	19.33	50.5	22.6

Minimum of index = 2 for the two pairs  $\{i_3, i_5\}$  and  $\{i_4, i_5\}$ .

Aggregation of  $i_3$  and  $i_5$  (fig. 4), hence the point  $l_{14}$  and the *cloud of 6 points* (fig. 5).

- **Step 5.** Aggregation index between  $l_{14}$  and the 5 other points

	$i_4$	$i_6$	$l_{11}$	$l_{12}$	$l_{13}$
$l_{14}$	3.33	31.07	17.33	13.00	16.4

 $\rightarrow$  aggregation of  $l_{12}$  and  $i_4$  at level 2.67 (fig. 5), hence the point  $l_{15}$  and the *cloud of 5 points* (fig. 6).

- **Step 6.** Aggregation index between  $l_{15}$  and the 4 other points

	$i_6$	$l_{11}$	$l_{13}$	$l_{14}$
$l_{15}$	12.03	12.49	20.61	11.33

→ aggregation of  $l_{15}$  and  $l_{14}$  at level 11.33 (fig. 6), hence the point  $l_{16}$  and the *cloud of 4 points* (fig. 7).

- **Step 7.** Aggregation index between  $l_{16}$  and the 3 other points

	$i_6$	$l_{11}$	$l_{13}$
$l_{16}$	21.67	15.57	20.86

→ aggregation of  $l_{16}$  and  $l_{11}$  at level 15.57 (fig. 7), hence the point  $l_{17}$  and the *cloud of 3 points* (fig. 8).

Figure 7

## • Step 8.

Figure 8

The three-class partition  $\mathcal{A}$  ( $l14$ ),  $\mathcal{B}$  ( $i6$ ),  $\mathcal{C}$  ( $l17$ ) (already studied) with mean points  $A$  ( $l13$ ),  $B$  ( $i6$ ),  $C$  ( $l17$ ) (fig. 8).

## • Step 9.

Table of the within-contributions of the 3 pairs of points

(distance) <sup>2</sup>	weight	Contribution
$AB^2 = 290$	$\widetilde{n}_{AB} = \frac{1}{\frac{1}{2} + \frac{1}{1}} = 2/3$	$\text{Cta}_{(A,B)} = \frac{2/3}{10} \times 290 = 19.33$
$AC^2 = 226.33$	$\widetilde{n}_{AC} = \frac{1}{\frac{1}{2} + \frac{1}{7}} = 14/9$	$\text{Cta}_{(A,C)} = \frac{14/9}{10} \times 226.33 = 35.21$
$BC^2 = 284.90$	$\widetilde{n}_{BC} = \frac{1}{\frac{1}{1} + \frac{1}{7}} = 7/8$	$\text{Cta}_{(B,C)} = \frac{7/8}{10} \times 284.90 = 24.93$

At this step, we group A and B at level 19.33 (fig. 9).

Figure 9

# Successive Steps of the AHC

$l$	$\delta_l$	clusters	$n$	class description	Between Var	$\eta_l^2$
$l_{19}$	38.095	$l_{18} \ l_{17}$	10	$i_9 \ i_{10} \ i_3 \ i_5 \ i_4 \ i_7 \ i_8 \ i_6 \ i_1 \ i_2$	$l_{19}$	
$l_{18}$	19.333	$l_{13} \ l_6$	3	$i_6 \ i_1 \ i_2$	$l_{18}$	38.10 .414
$l_{17}$	15.571	$l_{16} \ l_{11}$	7	$i_9 \ i_{10} \ i_3 \ i_5 \ i_4 \ i_7 \ i_8$	$l_{17}$	57.43 .624
$l_{16}$	11.333	$l_{15} \ l_{14}$	5	$i_3 \ i_5 \ i_4 \ i_7 \ i_8$	$l_{16}$	73.00 .793
$l_{15}$	2.667	$l_{12} \ l_4$	3	$i_4 \ i_7 \ i_8$	$l_{15}$	84.33 .917

$l_{11}$	0.2	$l_{10} \ l_9$	2	$i_9 \ i_{10}$	$l_{11}$	91.80 .998
						92.00 1

Sum of the 9 level indices = 92 (variance of the cloud).

Between-variance of the 2-class partition = 38.095.

Between-variance of the 3-class partition  
 = 38.095 + 19.333 = 57.43, etc.

## IV.6. Interpretation of clusters

Active variables then supplementary variables

### Categorical variables

#### 1. **descriptive criterion:**

*Categories over-represented:*

The relative frequency of the category in the cluster ( $f_c$ ) is 5% higher than the frequency in the whole set ( $f$ ) or is twice the one in the whole set.

$$f_c - f > 0.05 \quad f_c/f > 2$$

*Categories under-represented:*  $f_c - f < -0.05 \quad f_c/f < 2$

#### 2. **inductive criterion:**

The hypergeometric test of comparison of the frequency to the reference frequency is significant.

## Numerical variables

Variables retained for the interpretation:

1. **descriptive criterion:**

$$\frac{\text{mean for the cluster} - \text{mean for the overall set}}{\text{standard deviation for the whole set}} \geq 0.5$$

or

$$\frac{\text{mean for the cluster} - \text{mean for the overall set}}{\text{standard deviation for the whole set}} \leq -0.5$$

2. **inductive criterion:**

The combinatorial test of comparison of the mean in the cluster to the overall mean is significant.

## IV.7. Other Aggregation Indices

- **Minimal jump.** the smallest distance between the elements of the 2 clusters = *single linkage clustering*.
- **Maximal jump.** The largest distance between elements of the two clusters = *diameter index*, or *complete linkage clustering*.
- **Mean distance .** Weighted mean of distances between the points of 2 clusters = *average linkage clustering*.

## IV.8. Divisive Hierarchical Clustering

Start with one cluster and, at each step, split a cluster until only one–element clusters remain.

In this case, we need to decide which cluster will be split at each step and how to do the splitting.

**Methods:** CHAID and CART

# V — Specific MCA

and

# Class Specific Analysis (CSA)

This text is adapted from Chapter 3 (§3.3) of the monograph  
*Multiple Correspondence Analysis*  
(QASS series n°163, SAGE, 2010)

# V.1. Introduction

- *Specific MCA (SpeMCA)* consists in restricting the analysis to *categories of interest*.
- *Class Specific Analysis (CSA)* consists in analyzing a *subset of individuals* by taking the whole set of individuals as a reference.

## V.2. Specific MCA

The active categories are the *categories of interest*.

The excluded categories, called *passive categories*, are:

- *Infrequent categories*
  - remote from the center
  - contributing too much to the variance of the question
  - too influential on the determination of axes
- *Junk categories*: categories of *no-interest* not representable by a single point

## Cloud of individuals

If for active question  $q$ ,

- $i$  chooses active category  $k$  and  $i'$  active category  $k'$ , then the distance is unchanged:

$$d_q^{2'} = d_q^2(i, i') = \frac{1}{f_k} + \frac{1}{f_{k'}}$$

- $i$  chooses active category  $k$  and  $i'$  passive category  $k'$ :

$$d_q^2(i, i') = \frac{1}{f_k} \text{ (dropping } \frac{1}{f_{k'}})$$

*Geometric viewpoint:*

→ projection of the cloud onto a subspace of interest.

# Cloud of categories

subcloud of categories of active questions with weights and distances unchanged.

$K'$ : set of *active* categories of active questions

$K''$ : subset of *passive* modalities of active questions

$K$ : set of *active and passive* categories of active questions

$Q'$ : set of active questions without passive categories

# Properties

- **Dimension of the cloud:**  $K' - Q'$

(number of active categories minus number of questions without passive categories).

- **Specific overall variance:**

$$\frac{K'}{Q} - \sum_{k \in K'} \frac{f_k}{Q} = \text{sum of eigenvalues}$$

- **Modified rates:**

calculate  $\bar{\lambda}$  = specific variance divided by the number of dimensions of the cloud;

$$\text{modified rates} = \frac{(\lambda - \bar{\lambda})^2}{\sum (\lambda - \bar{\lambda})^2} \quad (\sum \text{ over eigenvalues } > \bar{\lambda}).$$

# Principal axes and principal variables

- Coordinates of individuals on an axis :

Mean = 0      Variance = specific eigenvalue

- Coordinate of categories on an axis:

- Mean of coordinates of *active and passive* categories (weighted by the relative weight  $f_k/Q$ ) = 0

- Raw sum of squares of coordinates of *active* categories (weighted by  $p_k = f_k/Q$ ) =  $\lambda$

## *Fundamental properties of standard MCA are preserved:*

- the principal axes of the cloud of individuals are in a one-one correspondence with those of the cloud of categories,
- the two clouds have the same eigenvalues.
- Link between the two clouds:

$$\bar{y} = \sqrt{\lambda} y$$

( $y$ : principal coordinate of category  $k$   
 $\bar{y}$ : principal coordinate of category mean–point  $k$ )

## V.3. Class Specific Analysis (CSA)

Study of a class (subset) of individuals with reference to the whole set of individuals.

We seek to

- determine the specific features of the class,
- compare the *class subcloud* with the *initial cloud*.

*This is possible only if the class subcloud and the initial cloud are in the same Euclidean space.*

# Class specific cloud of individuals

The distance between 2 individuals of the class is the one defined from the whole cloud.

# Class specific cloud of categories

The distance between two categories points depends on

- the relative frequencies of the categories in the class,
- the relative frequencies of the categories in the whole set,
- the conjoint frequency of the pairs of categories in the class.

# Principal axes and principal variables

- Coordinates of individuals on an axis :

Mean = 0      Var = specific eigenvalue

- Coordinate of categories on an axis (weighted by the relative weight in the whole set):

Mean = 0      Var = specific eigenvalue
